ABSTRACT

Objectives: In this randomized split-mouth clinical trial the survival rate and quality of survival of indirect resin composite and ceramic laminate veneers were evaluated.

Methods: A total of 48 indirect resin composite (Estenia; n = 24) and ceramic laminate veneers (IPS Empress Esthetic; n = 24) were placed on maxillary anterior teeth. Veneer preparations with incisal overlap were performed using a mock up technique. Survival of the restoration was considered the primary outcome measure and reported using Kaplan-Meier statistics and survival curves compared by means of Log Rank (Mantel-Cox) test. After luting, restorations were evaluated by calibrated operators at baseline and every year thereafter, using modified USPHS criteria and compared by means of Mann-Whitney U test.

Results: In total, 6 failures were observed, consisting of debonding (n = 3) and fracture (n = 3), all in the group of the indirect resin composite laminate veneers. Cumulative chance on survival after 10 years of the indirect resin composite and ceramic veneers was 75% (se 3,8%) and 100% respectively (p = 0.013). Of the surviving 42 laminate veneers, the variables ‘color match’ (p = 0.002), ‘surface roughness’ (p = 0.000), ‘fracture of the restoration’ (p = 0.028), and ‘wear of the restoration’ (p = 0.014), were significantly less favourable among the composite laminate veneers as well.

Conclusions: The ceramic veneers on maxillary anterior teeth in this study performed significantly better compared to the composite indirect laminate veneers after a decade, both in terms of survival rate and in terms of quality of the surviving restorations.

Clinical Relevance: When indicated, anterior ceramic laminate veneers may be preferred over indirect composite laminate veneers.

1. Introduction

Laminate veneer restorations are indicated for different esthetic reasons as a minimal invasive treatment concept. Based on the literature there is no consent as to which material should be used as the restorative material, composite or ceramic [1,2]. Some attempts have been made to compare these materials in vivo, however, no comparison was made in vivo in a split mouth environment with over 10 years of follow up [1,3].

Survival rates of ceramic laminate veneers range between 82–96%

after 10–21 years [4–9]. Fracture of ceramic material (5.6–11%) and marginal defects (12–20%) were the main reasons of failure [4,6,10–14]. Success rates are reported to decrease due to poor marginal quality and discoloration which contained 18–25% up to 10 years of function.

Indirect composite restorations are easy to lute and repair, have higher flexural modulus, are cost effective and less abrasive to the antagonistic teeth [15]. Contemporary particulate filler composites (Estenia, Kuraray Co., Tokyo, Japan) contains up to 92 wt% colloidal silica spheres with 16 wt% superfine microfillers, grain size of 0.02 μm, and

76 wt% microfillers, grain size of 2 µm in urethane tetramethacrylate (UTMA) resin matrix. Previous indirect composite resin materials contained merely 50–80 weight% of fillers [16,17]. In addition, UTMA resin matrix which contains four functional urethane methacrylates resulting in a higher crosslinking density than other materials [17]. The higher filler content increases both strength and optical properties, but make the material more brittle as well.

Direct comparison between different material options for laminate veneers were only performed in few studies with relatively short follow-up periods. Therefore, the Cochrane Collaboration concluded that there is no evidence as to which material performs better [2]. In an *in vivo* study by Meijering et al. [1] different materials were compared for laminate veneers; direct composite, indirect composite and ceramic. Survival rates were 6%, 13% and 0% respectively after a mean follow up period of 1.7 years. Relative failures were not different among the indirect composite and ceramic restorations. In a split mouth randomised clinical trial with 3 years of follow up similar failure rates were obtained for indirect resin composite laminate veneers (13%) [3]. Relative failures were seen but not considered significant between the two materials either, except for surface roughness [3].

Due to aging of dental materials, differences between materials could be expected. Exposure to smoking, food, acidic beverages, temperature changes, function of the teeth, saliva and biofilm will affect various materials differently. Although composite materials are known for their degradation, ceramic or the glaze layer of the ceramic will also deteriorate over time due to acidic influences and functional wear [18,19]. Degradation of the surface polish or smoothness will not only affect the esthetic appearance, but also biofilm accumulation [20] and wear of surrounding or opposing teeth [21–23].

The objective of this randomized clinical trial was to evaluate the clinical performance of maxillary anterior laminate veneers made of particulate filled composite and ceramic in a split-mouth design after a mean observation period exceeding 10 years of clinical service. Primary outcome parameter was survival of the restoration, secondary outcome parameter was the quality of survival. The null hypothesis tested was that both laminate materials would function similarly.

2. Materials and methods

2.1. Study design

This is the follow up study of data presented in our previous article [3]. To avoid possible disturbing differences in case when distinct degrees of tooth discoloration would occur between restorations of different materials, a modified split mouth design was employed in which the central incisors and the symmetrical other teeth received the same type of restoration. Randomization was performed using the flip of a coin for the choice of material. For this observational study the STROBE guidelines were followed.

2.2. Inclusion and exclusion criteria

Potential candidates were at least 18 years old, able to read and sign the informed consent document, physically and psychologically able to tolerate conventional restorative procedures, having no high caries risk, periodontal or pulpal diseases, having teeth with good restorations, require esthetic improvement of at least 2 anterior teeth, not allergic to resin-based materials, not pregnant or nursing, and willing to return for follow-up examinations as outlined by the investigators. Between June-2008 and November-2010, a total of 11 patients ranging in age between 20 and 69 years (8 female, 3 male, mean age: 54.5 years) could be recruited and received 48 indirect composite ($n = 24$) and ceramic laminate veneers ($n = 24$). Alternative treatment options were discussed. All patients provided informed consent as required by the ethical committee of the University Medical Centre Groningen review board (Clinical Trial identification number: NCT03145597).

2.3. Tooth preparation

Treatment planning was performed using digital photos, and stone casts. Shade was determined using different shade tabs under standard conditions (6500 K, 8 light intensity, Longlife, Aura, The Netherlands) in the dental laboratory. A wax set-up was made on the plaster model using the mock-up technique [9]. The wax set-up was used to communicate on the correction of the form and position of the teeth and also to evaluate the expectations of the patient.

Magnifying microscope (x3.4 - 21.3) (Opmipico, Zeiss, Sliedrecht, The Netherlands) was used for minimal preparations. Ball-shaped diamond burs (ISO 801 018, Diatech, Altstätten, Switzerland) were used to mark preparation depths through the set-up. The labial surfaces were axially reduced by 0.3-0.5 mm. Tapered round-ended diamond burs (ISO 856 018, Diatech) were used for uniform preparations. An incisal overlap of 1–1.5 mm was prepared on all cases. At the cervical area, a shallow chamfer finish line (0.5 mm) was created equi- or supra-gingival to maintain good periodontal health. A shallow chamfered marginal finish line extended inter-proximally to hide the restoration margins up to contact area.

All internal angles were smoothed to reduce stress concentration. On the palatal aspect, a right-angled contour (butt joint) between the incisal edge and the palatal surface was achieved. Impressions were then made using a polyether impression material (Impregum, 3 M ESPE, St. Paul, MN, USA). Temporary veneers were made chair-side using a spot-etch technique and auto-polymerized bis-acryl (Structur SC, Voco, Cuxhaven, Germany).

One dental technician made all laminate veneers. Leucite reinforced glass ceramic (IPS Empress Esthetic, Ivoclar Vivadent, Schaan, Liechtenstein) were processed according to the manufacturer's instructions using the IPS Empress layering and lost wax technique. After wax-up, a cut-back of 0.2-0.8 mm was performed to allow for layering of the veneering ceramic.

The indirect composite laminate veneers (Estenia C&B, Kuraray, Tokyo, Japan) were fabricated using the layering technique following the manufacturer's instructions. They were heat- (100–110 °C for 15 min) and photo-polymerized (400–515 nm for 270 s) using a special polymerization device (Heat-curing-110, Toesco, Yoshida, Japan) according to the manufacturer's recommendations.

Both ceramic and resin composite laminate veneers were hand polished using diamond burs and silicone rubber points (3044HP-30044HP Ceragloss, Edenta, St. Gallen, Switzerland) and diamond pastes with brushes (Estenia C&B polishing compound and Yeti Diaglaze).

2.4. Luting

Form, adaptation and shade match of the restorations were checked clinically using try-in pastes (Variolink Veneer Try-in Paste, Ivoclar Vivadent).

After cleaning with 99% isopropanol, intaglio surfaces of the laminates were etched with 4.9% hydrofluoric acid (IPS Ceramic etching gel, Ivoclar Vivadent) for 1 min, washed thoroughly for 1 min and dried with oil-free compressed air. Since etching with hydrofluoric acid leaves a significant amount of crystalline debris precipitate at the ceramic surface, 4 laminate veneers were ultrasonically cleaned in distilled water for 5 min. Thereafter, the adhesive surfaces were silanized (Monobond S, Ivoclar Vivadent) for 1 min. After silanization, adhesive resin (Excite, Ivoclar Vivadent) was applied, air-thinned but not polymerized.

The intaglio of the indirect composite laminate veneers was tribochemically silica coated (30 µm SiO₂, CoJet-Sand, 3 M ESPE) using an intraoral air-abrasion device (Dento-Prep, RØNVIG A/S, Daugaard, Denmark) at a pressure of 2.5 bar from a distance of approximately 10 mm for 20 s. They were then silanized with 3-methacryloxypropyl-trimethoxy silane coupling agent (MPS) (ESPE-Sil, 3 M ESPE AG) and

waited for its evaporation for 5 min. After silanization, adhesive resin (Excite, Ivoclar Vivadent) was applied, air-thinned but not polymerized.

All teeth to be veneered were isolated using a split-rubberdam technique. Contour strips (Contour-Strip, Ivoclar Vivadent) were placed interproximal to perform a smooth restoration outline in the approximal-cervical area. The prepared teeth were first cleaned with fluoride-free pumice (Pumice Flour, Dux, Utrecht, The Netherlands) using a polishing brush (Polishing brush, Coltène/Whaledent, Altstätten, Switzerland).

Enamel and dentin were etched with 37% H₃PO₄ (Total Etch, Ivoclar Vivadent, Schaan, Liechtenstein) for 15–30 seconds. After rinsing for 30 s and air-drying, the adhesive resin (Excite, Ivoclar Vivadent) was then applied on both the tooth and the restoration surfaces with a microbrush for 15 s, air-thinned but not polymerized.

Laminate veneers were luted using a photo-polymerizing resin composite cement (Variolink Veneer, Ivoclar Vivadent). Composite was applied to the inner surface of the laminates. After placement, initially, they were photo-polymerized with an LED lamp (Bluephase 20i, Ivoclar Vivadent) for only 3 s at the buccal surface to ensure stabilization of the veneer. The light output was at least 800 mW/cm² in all applications. Gross excess composite at the margins was removed immediately with the aid of brushes, scalers and dental floss (Oral-B, Rotterdam, The Netherlands). Application of glycerine gel (Liquid-Strip, Ivoclar Vivadent) at the margins ensured oxygen inhibition during polymerization. Buccal, oral, and proximal surfaces were further polymerized for 40 s. After rinsing the glycerine gel, excess material was removed with hand-instruments and finishing burs. Restoration margins were further polished with silicone polishers (Astropol FP, HP, Ivoclar Vivadent) and interproximal polishing strips (Soft-Lex Finishing Strips, 3 M ESPE) at 7.500–10.000 rpm under water. One clinician placed all restorations. Finally, the occlusion was checked in protrusive and lateral movements of the mandible. The goal was to reach anterior guidance and lateral protection in all cases. Patients were given information on how to clean the restorations and teeth, on diet (no restrictions with food or drinks), no nail biting and parafunctional habits (providing a night guard).

2.5. Evaluation

Restorations were clinically evaluated at baseline and thereafter by two calibrated observers who were blinded to the objective of this study. Caries, debonding and fracture to failure were considered as absolute failures. Patients were also questioned about possible post-operative complaints. Both observers evaluated the restorations independently, according to the modified United States Public Health Service (USPHS) criteria (Table 1). The restorations were visually inspected with dental mirror and probe. After data collection, in case of discrepancies in scoring, restorations were evaluated again, a consensus was reached and this was accepted as the final score. Patients were instructed to call upon any kind of failure. Digital pictures (1:1) were made after placement of the veneers and during follow-up sessions. In representative cases, an impression (Ultra-Light and Heavy body Aquasil, Dentsply) was taken from the two laminate veneers after cleansing the surface with absorbent paper and sodium hypochlorite 0.5%. Impressions were poured with cold mounting epoxy resin (Epoxy-Cure, Buehler, IL, USA) then sputter-coated with a 3 nm thick layer of gold (80%) / palladium (20%) (90 s, 45 mA; Balzers SCD 030, Balzers, Liechtenstein) and analyzed using cold field emission Scanning Electron Microscope (SEM) (LyraTC, Tescan, Brno, Czech Republic). Images were made at 15 kV at a magnification of x22 to x2500.

2.6. Statistical analysis

Survival analyses were performed with statistical software program (SPSS 23.0; SPSS Inc, Chicago, IL, USA) using Kaplan-Meier and Log

Table 1

List of modified United States Public Health Service (USPHS) criteria used for the clinical evaluations of the laminate veneers.

| Category | Score | Criteria |
|---------------------------|-------|---|
| Adaptation | 0 | Smooth Margin |
| | 1 | All margins closed or possess minor voids or defects (enamel exposed) |
| | 2 | Obvious crevice at margin, dentin or base exposed |
| | 3 | Debonded from one end |
| | 4 | Debonded from both ends |
| Color match | 0 | Very good color match |
| | 1 | Good color match |
| | 2 | Slight mismatch in color or shade |
| | 3 | Obvious mismatch, outside the normal range |
| Marginal Discoloration | 0 | Gross mismatch |
| | 0 | No discoloration evident |
| | 1 | Slight staining, can be polished away |
| | 2 | Obvious staining, cannot be polished away |
| Surface roughness | 3 | Gross staining |
| | 0 | Smooth surface |
| | 1 | Slightly rough or pitted |
| Fracture of restoration | 2 | Rough, cannot be refinished |
| | 3 | Surface deeply pitted, irregular grooves |
| | 0 | No fracture |
| | 1 | Minor crack lines over restoration |
| | 2 | Minor chippings of restoration (1/4 of restoration) |
| Fracture of tooth | 3 | Moderate chippings of restoration (1/2 of restoration) |
| | 4 | Severe chippings (3/4 restoration) |
| | 5 | Debonding of restoration |
| | 0 | No fracture of tooth |
| | 1 | Minor crack lines in tooth |
| Wear of restoration | 2 | Minor chippings of tooth (1/4 of crown) |
| | 3 | Moderate chippings of tooth (1/2 of crown) |
| | 4 | Crown fracture near cementum enamel line |
| | 5 | Crown-root fracture (extraction) |
| | 0 | No wear |
| Wear of antagonist | 1 | Wear |
| | 0 | No wear |
| Caries | 1 | Wear of antagonist |
| | 0 | No evidence of caries continuous along the margin of the restoration |
| Postoperative sensitivity | 1 | Caries evident continuous with the margin of the restoration |
| | 0 | No symptoms |
| | 1 | Slight sensitivity |
| | 2 | Moderate sensitivity |
| | 3 | Severe pain |

Rank (Mantel-Cox) tests to obtain the overall survival rate in relation to observation time. A nonparametric test (Mann-Whitney U test) was performed for the qualitative evaluation of the data. An alpha level of 0.05 for all statistical tests was set.

3. Results

5 Recalls were performed after baseline measurements and no drop-outs occurred, yielding to the evaluation of 48 indirect laminate veneers (Estenia: n = 24; IPS Empress Esthetic: n = 24)(Fig. 1). After including 11 patients, it was decided to stop the further inclusion of patients due to failures and differences seen in longevity between both groups. The mean observation time was 97 months with a minimum observation period of 89 months (n = 4) and up to a maximum of 120 months (n = 4). The distribution of the location of the restorations was as follows: 20 on central incisors, 18 on lateral incisors, and 10 on canines. Average treatment time for each restoration was noted to be approximately 120 min, regardless the treatment type. Two patients received occlusal splints after cementation, indicated because of parafunctional habits.

The cumulative chance of survival was 75% (se 3,8%) and 100% for

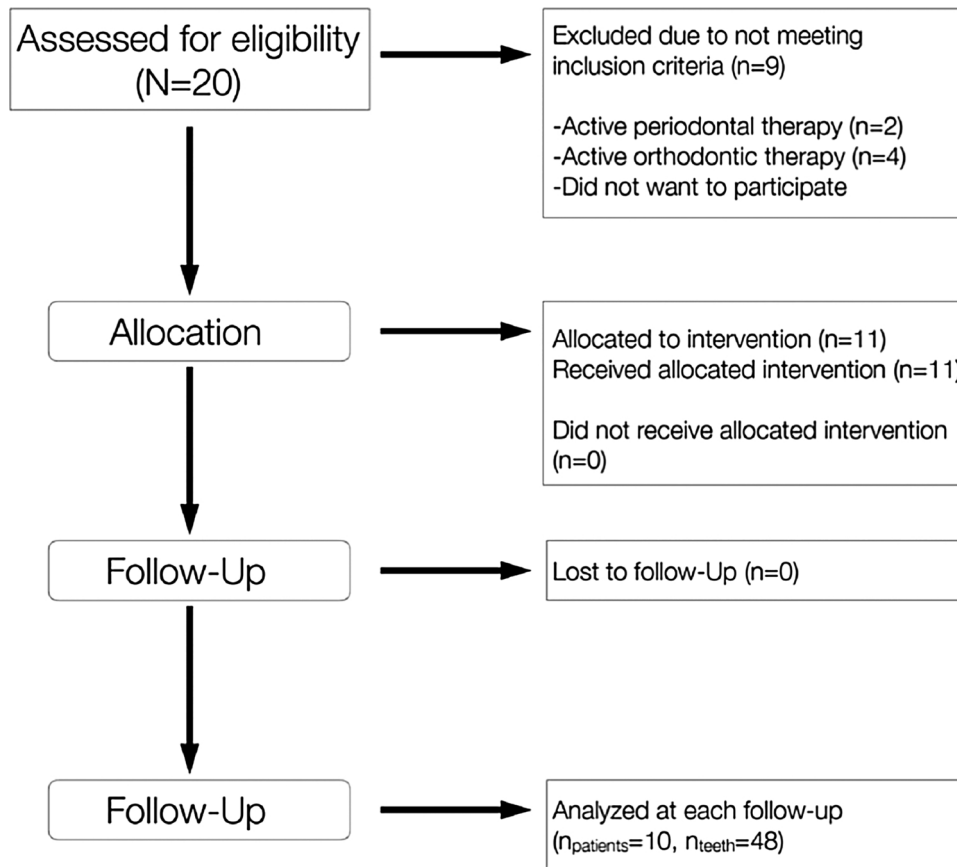

Fig. 1. CONSORT flowchart presenting the inclusion and exclusion criteria and the final characteristics of the patients recruited to participate in this study.

Fig. 2. Event-free survival rates of indirect resin composite and ceramic laminate veneers based on material up to 120 months (Estenia: 75% (se 3,8%); n = 24, events n = 6; IPS Empress Esthetic: 100%; n = 24, events n = 0).

the indirect composite and ceramic laminate veneers respectively after 10 years (120 months). Survival curves showed a statistically different distribution ($p = 0.013$) [Kaplan-Meier, Log Rank (Mantel-Cox) (CI = 95%)] (Fig. 2). A total of 6 absolute failures were observed, all in

the in the group of the indirect resin composite veneers in the form of debonding ($n = 3$) or fracture ($n = 3$). The debondings were a complete adhesive failure between the tooth and the luting cement, which occurred 11–25 months after cementation. Some of the composite

remained attached to the inner surface of the laminate restoration. After cleaning the adhesive surface, the debonded veneers were re-bonded but were not further evaluated and scored as a failure. All fractures occurred at the incisal area and were cohesive failures in the indirect composite material. The first fracture occurred on a tooth 11 (Fig. 4a), 13 months after delivery. The second laminate fracture occurred on a tooth 22 which was sound, 11 months after delivery. The third fracture occurred 6 years after placement after eating some bread.

Besides absolute failures, success was scored using the USPHS criteria (Table 2). Qualitative evaluation (success) showed some significance differences between laminates made of ceramic and indirect composite (Table 2). For all of these variables, the ceramic restorations were rated better. Of the 42 laminate veneers, minor voids and marginal discrepancies and defects were observed in 14 of the composite and 10 of the ceramic veneers (Adaptation-Score 1–2). Color match was significantly (Mann-Whitney $U = 324$, $p = 0.002$) different as the ceramic laminate veneers matched the surrounded teeth, composite restorations did not match for 8 laminate veneers ($p = 0.002$). Slight staining at the margins was seen more frequent with the composite laminate veneers ($n = 12$), however not significant ($p = 0.107$). Slightly rough surfaces (Surface roughness-Score 1) were significantly (Mann-Whitney $U = 444$, $p = 0.000$) more observed in the resin composite laminate veneer group ($n = 18$) until the final recall. These rough surfaces also experienced more plaque adhesion (Fig. 4b). Internal fractures without intervention were significantly (Mann-Whitney

$U = 292$, $p = 0.028$) more seen ($n = 6$, $p = 0.028$) in the indirect composite group, chippings of tooth material were more seen in the composite group as well however this was not significant different ($p = 0.06$). Wear of the restoration was significantly (Mann-Whitney $U = 303$, $p = 0.014$) more seen in the indirect composite group ($n = 7$, $p = 0.014$). Secondary caries, endodontic complications or wear of the antagonist were not observed in any of the cases. In total, 8 teeth showed post-operative sensitivity at baseline, as reported by the patient. All post-operative sensitivities disappeared after 2 weeks; at the final recall 2 teeth were somewhat sensitive to cold. SEM and digital pictures were used for surface evaluation as can be seen in Fig. 3. This particular patient had her laminate veneers for 9 years and differences in surface change between the two materials can be clearly seen. Gloss retention was better with the ceramic restorations which is also seen at the SEM analysis. Patients were not aware of the loss of gloss due to saliva over the restorative materials (Fig. 5a-b).

4. Discussion

In this randomized split mouth clinical trial, a comparison of indirect resin composite and ceramic laminate veneers was performed. This is the first clinical trial on anterior indirect restorations using two different restorative materials with a mean follow up of more than 8 years. The split mouth study design used removes a lot of inter-individual variability from the estimates of the treatment effect. The

Fig. 3. a–d. Example of a representative patient at 9 year follow up recall. A) The intra oral situation where the two central incisors are made of indirect composite and the laterals of ceramic. It can be clearly seen that the central incisors did not keep their gloss B) Overview of the central and lateral incisor using SEM C) A 2500 times magnification of the composite laminate veneer where the degradation can be clearly seen D) A 2500 times magnification of the ceramic surface where there is almost no degradation of the surface and remains smooth.

results presented cover observations up to 120 months of clinical function. In total 90% of the laminates required no intervention which could be considered as clinically acceptable. However, based on the significant differences in different aspects of success as well as the differences in survival rates the null hypothesis that there is no difference between the two restorative materials was rejected. Ceramic veneers performed significantly better than the indirect composite ones.

Six absolute failures occurred in this study of which 3 failed within the first 13 months of the study. The first failure occurred within the first year following luting and was a delamination of a composite laminate veneer on a canine where the substrate was predominantly dentin. In the literature, it is suggested that laminates bonded to large surfaces of dentin have a compromised survival rate and in such a situation requires an immediate dentin sealing, which was not performed in our study [24–26]. Increased fractures and chippings were noticed up to 8 times in studies where laminate veneers were made in patients with bruxing habits [7,27]. In this study, instructions to the patients were given at insertion of the laminate veneers regarding habits like nail biting and tearing materials with teeth. Two patients were provided with a hard acrylic resin occlusal appliance as they were suspected nocturnal bruxers. Patients were informed that there was a risk of fracture if compliance was inadequate. Another fracture after 12 months of insertion is probably related to function during protrusive and lateral excursive movements over teeth. Two debondings of composite laminate veneers occurred in the same patient (25 months after insertion) where both central incisors had received endodontic treatment prior to our study and the substrate was predominantly dentin again. All debonded laminate veneers could be rebonded to freshly cut dentin removing only 0.1 mm of dentin, performing a three step dentin bonding adhesive (Optibond FL, Kerr, Orange USA) and using a direct resin composite (HFO, Micrium, Avegno, Italy) as a cement [28,29]. All laminate veneers functioned until the end of the study but were scored as failure and were not screened for follow up evaluations.

Of the qualitative evaluation, most frequently observed differences

were the surface degradation and diminished gloss retention of the indirect resin composite material. All ceramic restorations remained smooth and their gloss until the final follow up. Both materials were processed in the laboratory and manufactured following the manufacturers' instructions by an experienced dental technician. The indirect composite material was photo- and heat-polymerized and both indirect materials were hand polished. Increased degradation of the material itself was more prone with the indirect composite material as is seen in other laboratory and clinical studies [30–33]. Fractures, chippings and wear were frequently seen at the incisal palatal aspect. This could be related to function and antagonist teeth articulating over these margin-material surfaces. One internal fracture in a ceramic laminate veneer was observed in the second year of function. This fracture was not treated or removed, but evaluated and remained stable until the end of the study.

Marginal quality was evaluated as adaptation of the veneer and discoloration of the margin. In different studies on ceramic laminate veneers as well as our study these were the mostly observed (adaptation: 56%; discoloration: 44%) qualitative complications [7,8,25,27,34,35] wear or degradation of the luting composite in the margins leads to discolorations but no caries was observed in any of the patients. Degradation of the margins was mostly observed in the palatal aspect and sometimes when the cervical outline was in dentin on the cervico-buccal aspect. Most of the marginal discolorations could be removed by polishing, however this was not performed as patients did not complain and further experimental evaluation could be performed.

Evaluation of surrounding tissues did not show significant differences in gingival health between the two materials. Only one patient had 0.5 mm of recession at a central incisor (ceramic) and a lateral incisor (indirect composite), which was probably related to brushing method and not to material properties.

When absolute failures are considered, the clinical performance of indirect resin composite and ceramic laminate veneers performed better up to 120 months. This finding is different from the first article which

Fig. 4. a–b. Patient after 1 and 5 years follow up A) Patient experienced a small chipping of tooth 11 after 1 year B) Patient after 5 years, note the difference in plaque adhesion and margin integrity between de composite and ceramic.

Fig. 5. a–b. Patient after 5 years follow up A) Patient with saliva on the teeth where the difference between composite and ceramic is not clearly noticeable B) Patient with dried teeth where the difference between composite and ceramic is clearly noticeable.

only had data up to 3 years with a mean observation time of 20.3 months. [3] Surface quality changes were more frequently observed in the composite veneer material that may require more maintenance over time.

In conclusion, the ceramic veneers on maxillary anterior teeth in this study performed significantly better compared to the composite indirect laminate veneers after a decade, both in terms of survival rate and in terms of quality of the surviving restorations.

Funding

The work was supported by the University Medical Center Groningen, the Netherlands, Department of Restorative Dentistry and Biomaterials.

Ethical approval

All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

Informed consent

Informed consent was obtained from all individual participants included in the study.

Disclosure statement

The authors did not have any commercial interest in any of the materials used in this study and each of the authors listed below declare no conflict of interest.

Acknowledgements

The authors extend their gratitude to Ivoclar Vivadent, Liechtenstein and Kuraray, Tokyo, Japan for supplying some of the materials used in this study. There are no conflicts of interest.
